# Particle Morphology Results from the Smoke Aerosol Measurement Experiment- Reflight

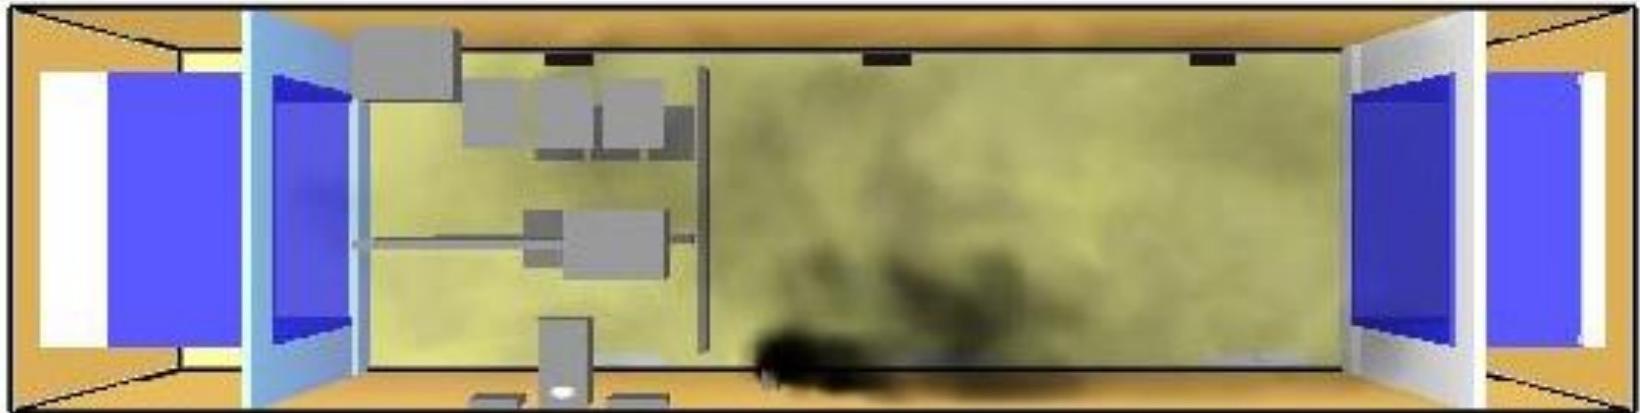

**David Urban, Gary Ruff, Paul Greenberg, Marit Meyer: NASA Glenn Research Center**

**Thomas Cleary, Jiann Yang: National Institute of Standards and Technology**

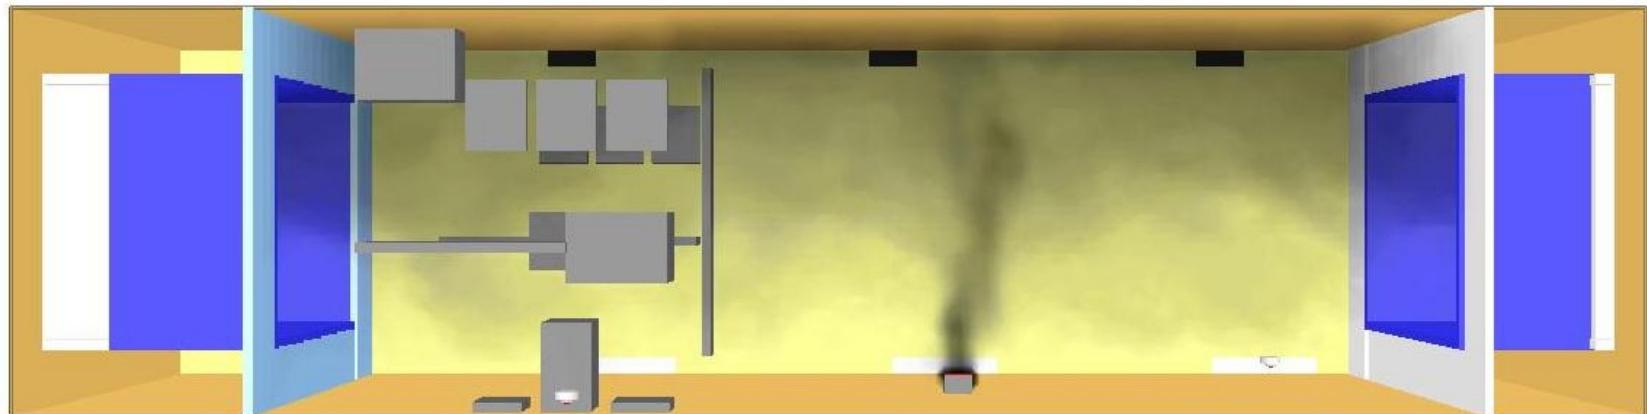

**George Mulholland: University of Maryland**

**Zeng-guang Yuan, Victoria Bryg: National Center for Space Exploration Research**

# Smoke Detection: Destiny Smoke Detection Simulation-25% Soot effect of gravity

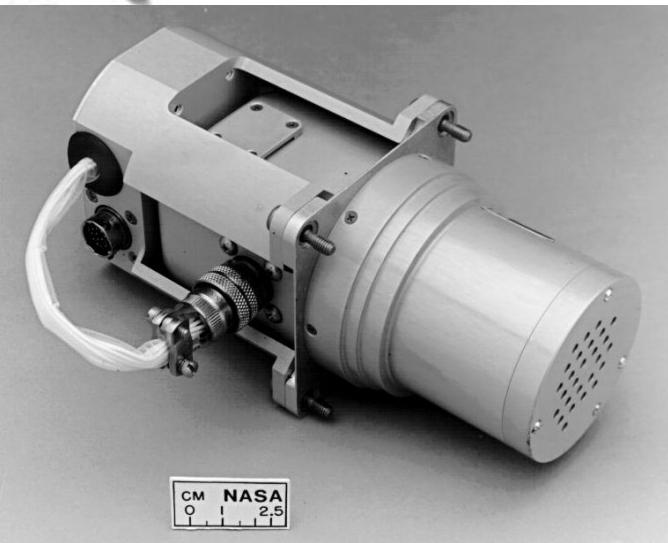

Low-gravity

Normal-gravity

# Background: Spacecraft Fire Detection

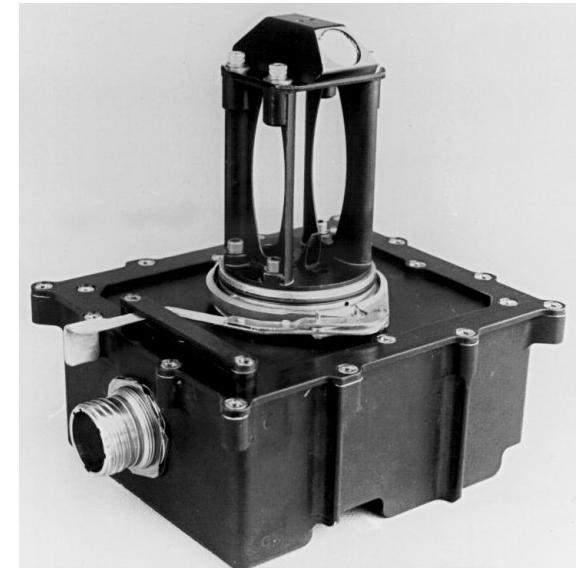

## STS Detector: sensitive < 1 micron

- dual-chamber ionization with inertial separator which rejects particles larger than 1-2 microns.
- fairly large power consumption (9 Watts)
- Installed in avionics air returns
- Developed in the late 70's when Ionization detectors were prevalent
- Decades of service with very few false alarms and no alarms.

## ISS detector: sensitive > 0.5 micron

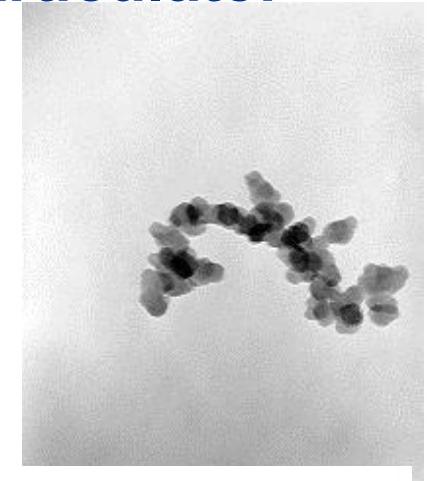

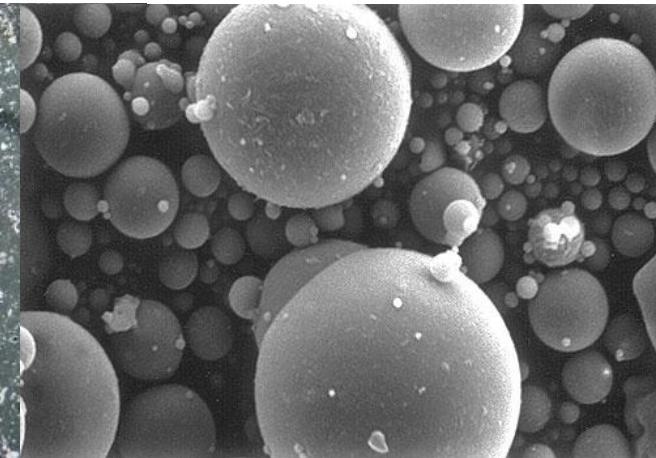

- 2-pass IR laser-diode forward-scattering detector (30 degrees) minimum reported sensitivity is 0.3  $\mu\text{m}$ .
- Low power (1.5 W)
- Installed in air ducts and in cabin area (with light shroud)
- Developed in the 90's and took advantage of the availability of stable diode light sources.
- Years of continuous ISS service with some false alarms and no alarms.

# Background: Types of Smoke

**“Smoke” encompasses several types of particulate:**

- Condensed steam/vapor
- Ash
- Soot
- Recondensed polymer solids
- Recondensed polymer liquids

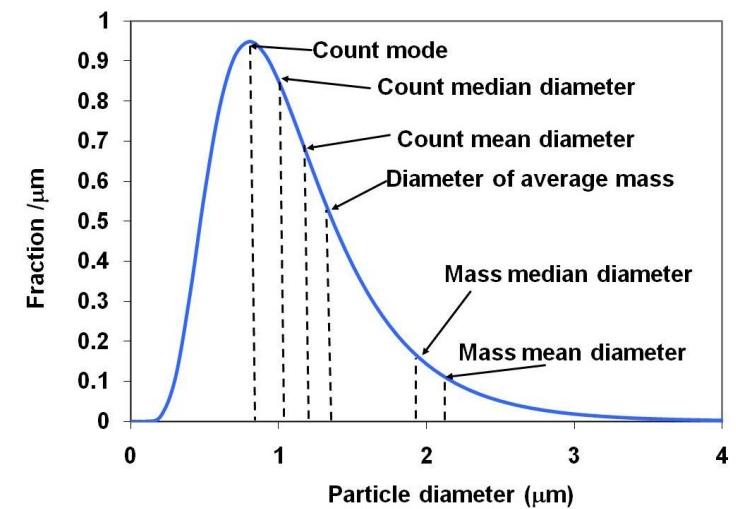

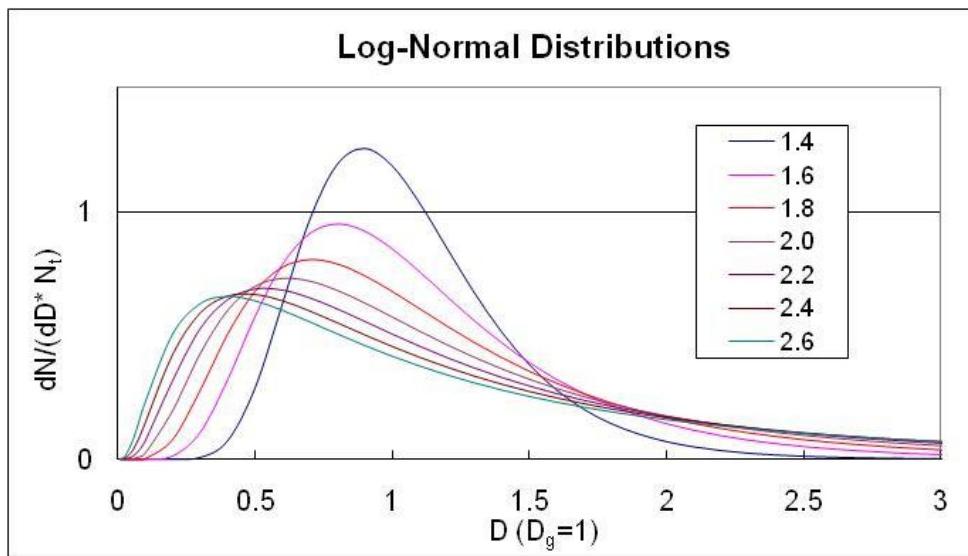

# Log-Normal Distribution

$$f_N(D) = \frac{N_t}{(2\pi)^{1/2} D \ln \sigma_g} \exp\left(-\frac{(\ln D - \ln D_g)^2}{2 \ln^2 \sigma_g}\right)$$

**Number is dominated by the smaller particles**

**Mass is dominated by the larger particles (tail)**

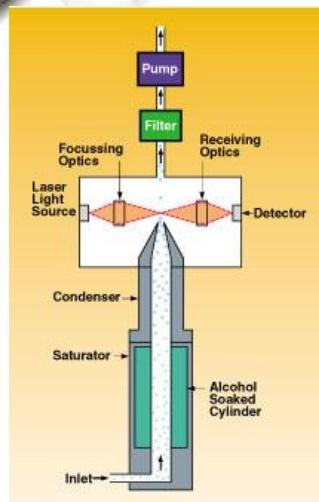

**Log-normal distribution  $\sigma_g = 1.6$ ,  $D_g = 1$**

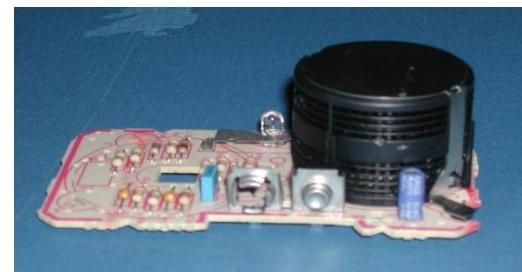

# SAME Experimental Diagnostic Measurements

All measure moments of the particle size distribution

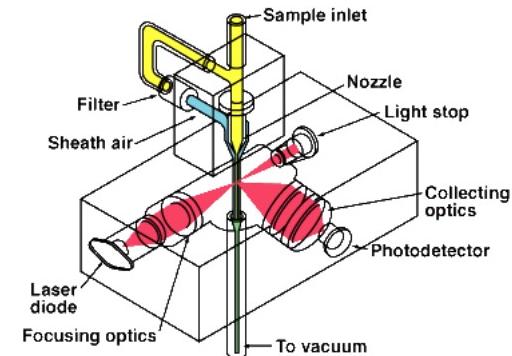

$$M_i = \int D^i f_N(D) dD$$

## High Temperature Lamp wick (Run 54)

# TEM Results

**TEM revealed several particle morphologies**

**Teflon and Pyrell: Aggregates**

**Teflon aggregates: numerous primaries of same dimension**

**Pyrell Aggregates: Primaries widely distributed in size**

**Kapton: single particles**

**Low temperature: produced very small and low TEM density particles**

**High temperature: TEM density increased**

**Silicone: No Tem visible particles**

**Lamp wick: Single particles, typically large**

**Aging showed a distinct elimination of the smallest particles**

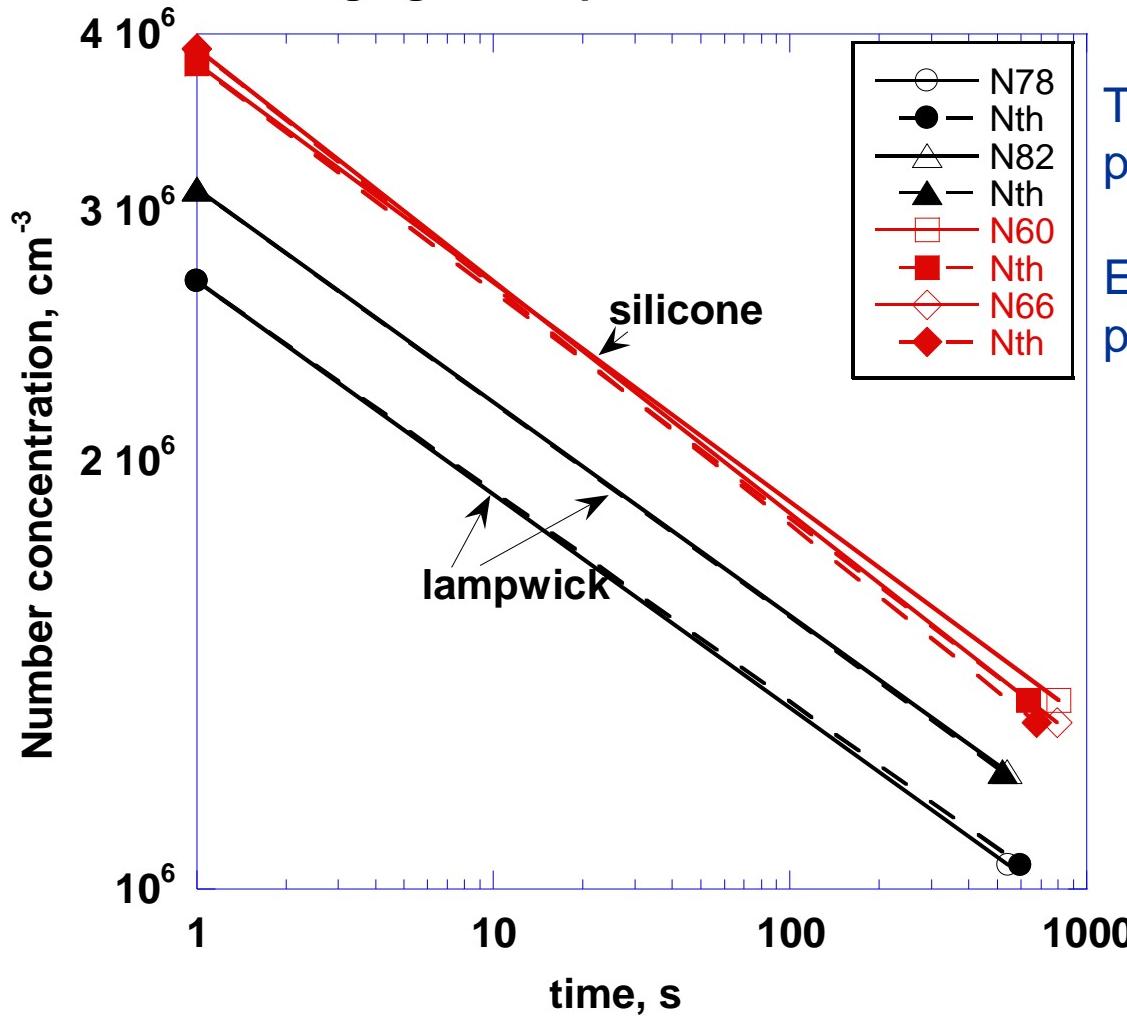

# SAME-1&R Results

	<b>Geometric Mean Diam. (nm)</b>	<b>Arithmetic Mean Diam. (nm)</b>	<b>Diam. of Average Mass (nm)</b>	$\sigma_g$
Kapton	47	62	106	2.07
Kapton aged	102	121	169	1.79
Lamp wick	103	142	271	2.23

# SAME Aging Results

Comparison of measured and predicted concentration after aging for lampwick and silicone smokes

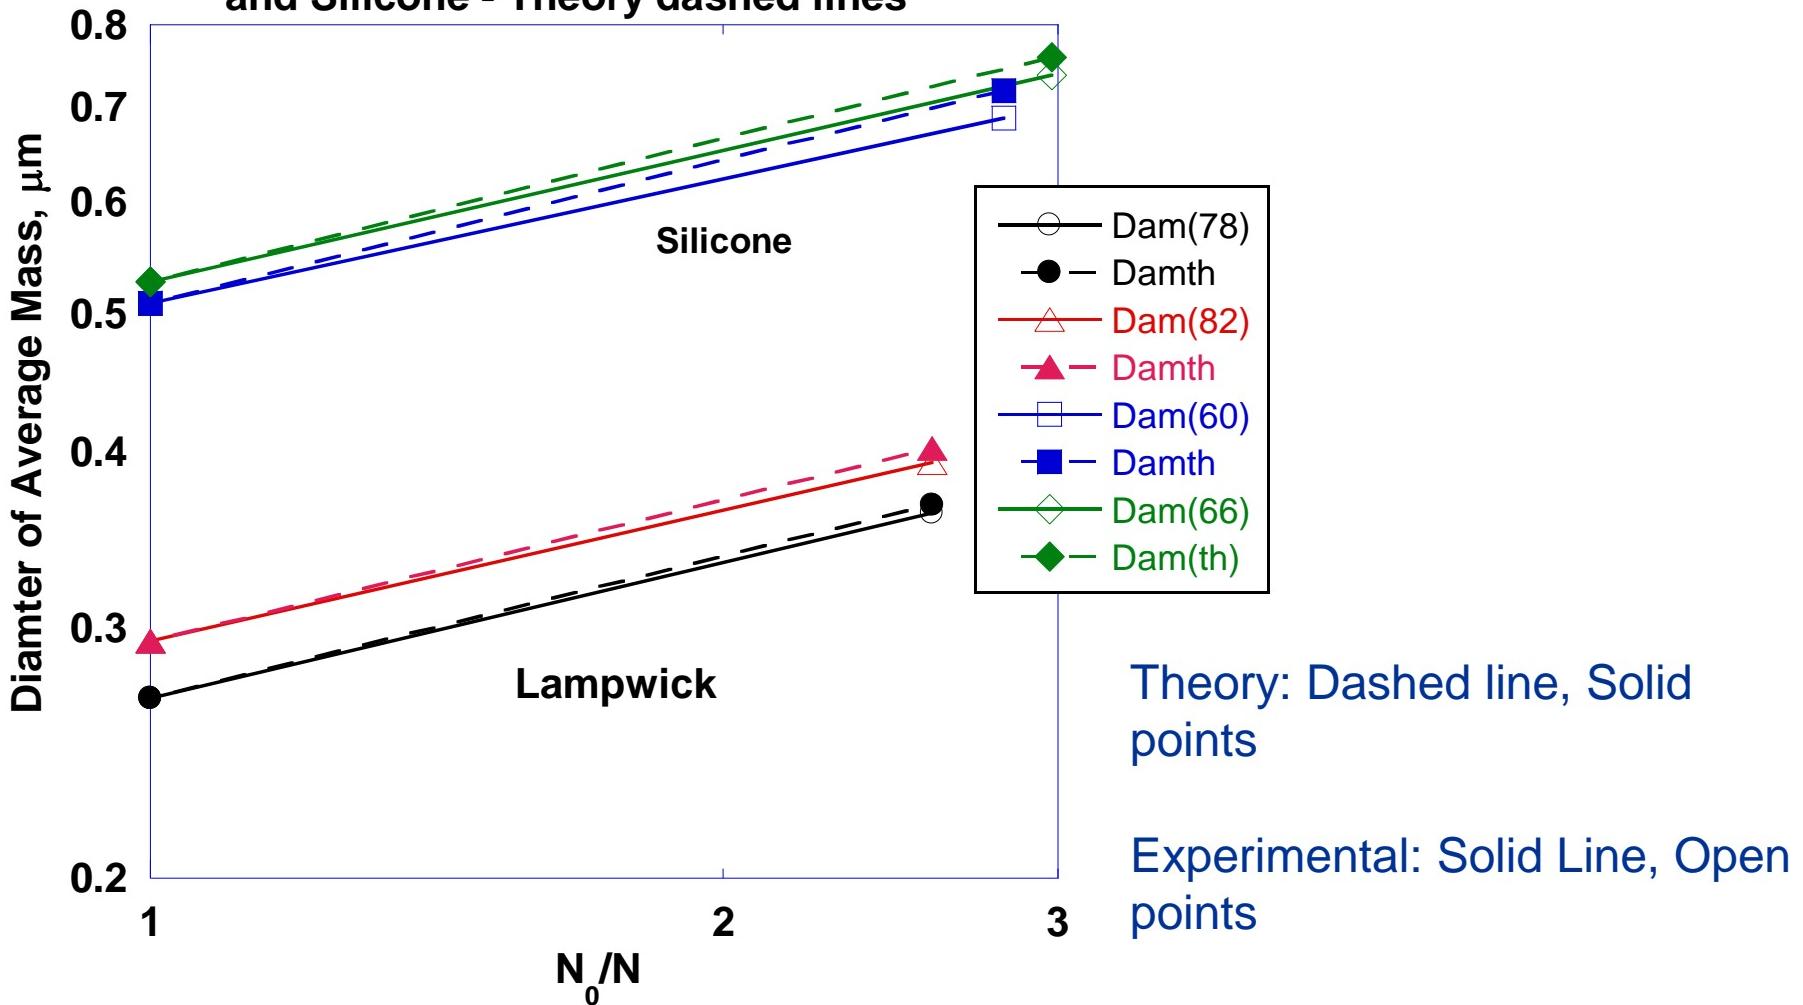

Theory: Dashed line, Solid points

Experimental: Solid Line, Open points

# SAME Aging Results

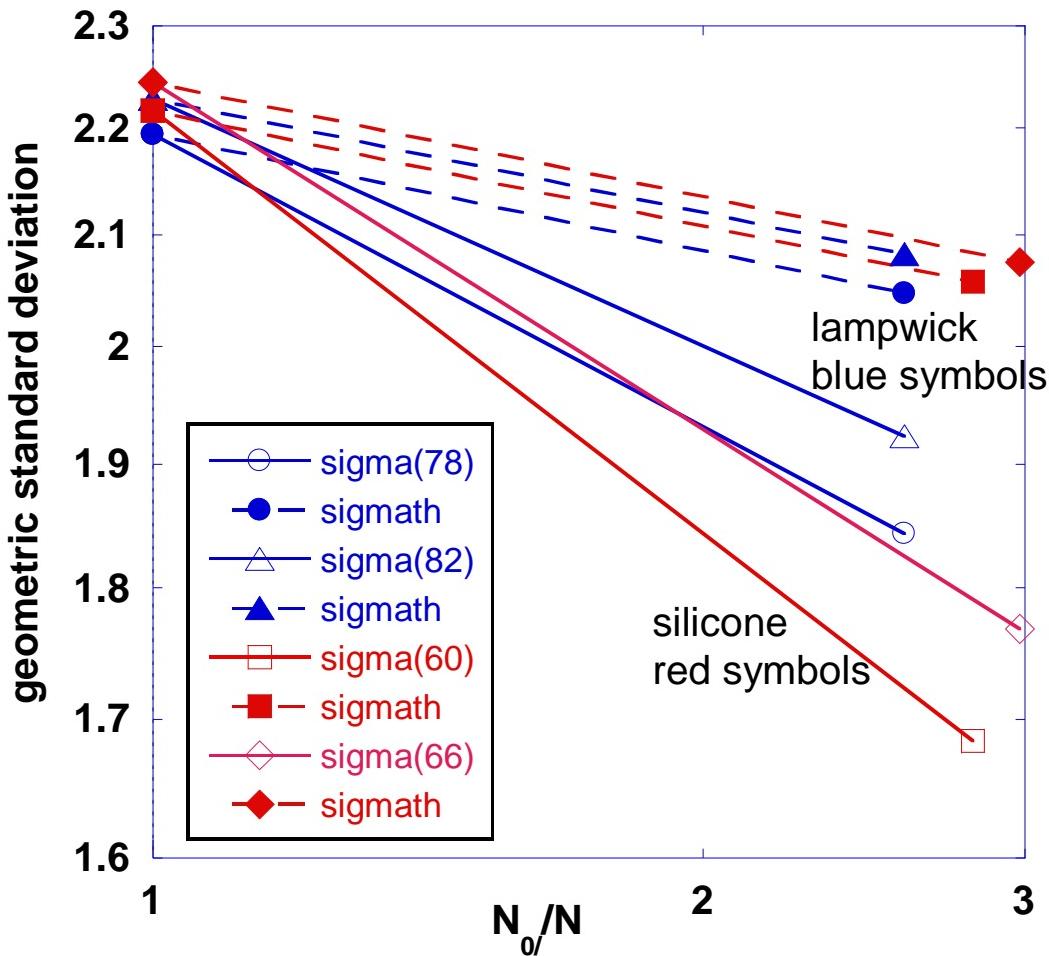

Effect of coagulation on  $D_{\text{am}}$  for Lampwick

and Silicone - Theory dashed lines

# SAME Aging Results

Effect of coagulation on  $\sigma_g$  for lampwick and silicone smoke - prediction values indicated by dashed lines

Theory: Dashed line, Solid points

Experimental: Solid Line, Open points

# SAME Aging Results

- For spacecraft materials, number counts decreased by a factor of 1.7 to 2.7 over 800 seconds.
- The measured and predicted number decreases agree within about 20 %.
- The best agreement between experiment and prediction is  $D_{avm}$  - agree within 4 %.
- The decrease in the geometric standard deviation is typically more than a factor of two greater than the predicted change.
- Aging results are relevant to partially sealed volumes and low air flow conditions.
- In all cases, aging resulted in approximately a factor of two decrease in number concentration and a factor of two increase in the number mean diameter with the exception of teflon

# Conclusions

- For the conditions tested, the materials emit most of their particulate in the submicron range.
- The ISS detector showed a relatively weak signal for some Teflon runs doubtless a result of the particle size.
- Particle morphology varies widely across the range of expected sample materials. Dependence on a single angle scattering device will be difficult.
- Aging results consistent with theory for number count and  $D_{avm}$  but not for  $\sigma_g$

# Implications and Future Work

- Dust rejection may be achievable by detecting at the sub-micron level.
- Given the effects of aging and the slow mixing seen in spacecraft, it is probably unwise to focus entirely on small particle sizes for fire detection
- Size selective smoke detection will improve reliability and false alarm rejection. Either by classifying the particles or by measuring multiple moments.
